Project 3: Unit 3

Suman Paudel 33

2024-05-01

Work 1

Use "airquality" data of R and locate median of "Temp" variable graphically

Hint:

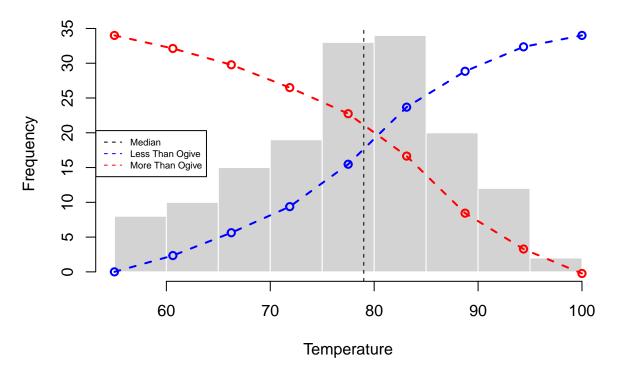

- 1. Divide the "Temp" variable into different class intervals using a statistical rule and get number of frequencies in each class interval
- 2. Get less than frequency data for less than ogive
- 3. Get more than frequency data for more than ogive
- 4. Plot less than and more than ogives in a single plot
- 5. Intersection of less than and more than ogive in the x-axis is the median
- 6. Check this value with median code of R

Solution Work 1

Load all of the necessary packages and data needed for Work 1.

```
# finding the class intervals using a statistical rule, such as Sturges' rule
intervals <- ceiling(log2(length(airquality$Temp)) + 1)</pre>
# creating class intervals using cut() function
temp_intervals <- cut(airquality$Temp, breaks = intervals)</pre>
# Get the frequencies in each class interval
freq <- table(temp_intervals)</pre>
# Calculate cumulative frequencies for each interval (ogives)
cum_freq_more_than <- cumsum(freq)</pre>
cum_freq_less_than <- rev(cumsum(rev(freq)))</pre>
cum_freq_more_than

Histogram with Cumulative Frequency Curves

Work 2

Work 2: Use "airquality" data of R and locate mode of "Temp" variable graphically

Hint:

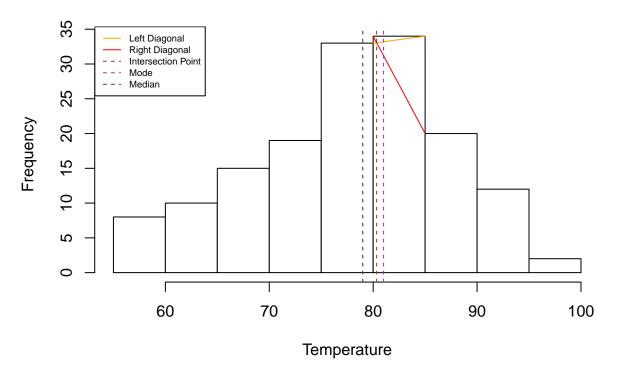

- 7. Get histogram of "Temp" variable
- 8. Draw a diagonal line from en edge of the largest bar to the tip of the opposite adjacent bar
- 9. Draw another diagonal line from other edge of the largest bar to the tip of of the opposite adjacent bar

- 10. Intersection of the two diagonal lines in the x-axis in the mode
- 11. Check this value with mode code of R

```
# Histogram of Temperature (Temp) variable
my_histogram <- hist(airquality$Temp,</pre>
                     main = "Histogram Of Temperature (Temp) Variable",
                     xlab = "Temperature",
                     ylab = "Frequency",
                     col = 'white')
# Find the location of the highest bar
max_bar_my_histogram <- which.max(my_histogram$counts)</pre>
# Get the leftmost and rightmost values of the highest bar
max left value my histogram <- my histogram$breaks[max bar my histogram]</pre>
max__right_value_my_histogram <- my_histogram$breaks[max_bar_my_histogram + 1]
# Get the highest count value
max_value_hist <- my_histogram$counts[max_bar_my_histogram]</pre>
# Get the locations of the left and right adjacent bars
loc_left_adj <- max_bar_my_histogram - 1</pre>
loc_right_adj <- max_bar_my_histogram + 1</pre>

```

Histogram Of Temperature (Temp) Variable

Work 3

Work 3: Use "SNA_School.csv" data and perform social network analysis of first and second variables

Hint:

- 12. Import and create a data frame "s" with first and second column of the data
- 13. Save it as network graph data object "net" with directed = T argument
- 14. Check number of vertices, edges, degree of "net" and interpret the carefully
- 15. Get histogram of net degree and interpret it carefully
- 16. Get network diagram of "net" and interpret it carefully
- 17. Get network diagram of "net" with kamada.kawai layout and interpret it carefully
- 18. Get hubs using hubs score and interpret it carefully
- 19. Get authority using authority score and interpret it carefully
- 20. Get community using the a special network diagram parameter and interpret it carefully

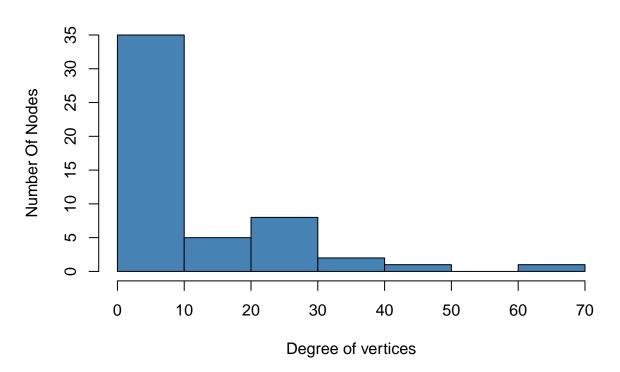

```
# load the necessary library
library(igraph)
library(readr)

# load the data from the current work space in the object sna then
sna <- read.csv('sna.csv')
head(sna)</pre>
```

```

Histogram of Net Degree

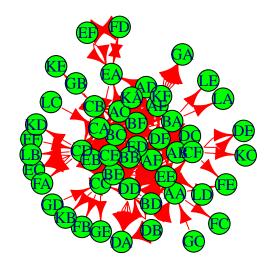

```
# Interpretation: The histogram shows the distribution of vertex degrees in the network.
# Most nodes have a degree between 0 and 10, indicating that they are connected to a
# small number of other nodes. There are fewer nodes with higher degrees,
# indicating that there are some nodes that serve as hubs
# or connectors within the network.
# Get network diagram of "net" and interpret it carefully

plot(net, edge.size = 15, edge.color = 'red',
    vertex.size = 20, vertex.color = 'green', )
```

```
# Interpretation: The network diagram shows the connections between nodes in the network.
# Nodes are represented as circles (vertices), and edges between them represent connections.
# The size and color of vertices and edges can be adjusted for better visualization.
# Here, edges are in red, and vertices are in green.

# Get network diagram of "net" with kamada.kawai layout and interpret it carefully
plot(net, edge.size = 10, edge.color = 'red',
    vertex.size = 20, vertex.color = 'green',
    layout = layout.kamada.kawai)
```

- # Interpretation: The Kamada-Kawai layout algorithm positions the nodes in the graph based on the # strength of their connections. Nodes that are more closely connected are placed closer together, # while nodes with weaker connections are positioned farther apart.
- # This layout can help reveal the overall structure and clustering of the network.
- # Get hubs using hubs score and interpret it carefully
 # Get hubs using hubs score and interpret it carefully
 hubs <- hub_score(net)\$vector
 hubs</pre>

# Average modularity of the partition
modularity <- modularity(communities)</pre>
modularity
## [1] 0.2987931
# Interpretation
# The number of communities gives you an idea of how fragmented or cohesive the network is.
# Larger networks may naturally have more communities.
# Community sizes indicate the distribution of nodes among the communities.
# You might have some dominant communities and some smaller ones.
# Modularity measures how well the network is divided into communities.
# Higher modularity values indicate a better division, with nodes more densely
# connected within communities and sparsely connected between communities.
```
